At Funding Societies, we use various data sources to assess the suitability of a borrower on our platform. We predict the willingness and ability of a borrower to repay us. This is a dataset of personal loans and the variables utilised to make lending decisions.

Your task would be to summarise the data and perform some initial analysis on it with a focus on the factors that drive lending decisions.

Feel free to use any software to process, analyse, model and present your findings. The idea here is to give you a realistic experience of the work we do. Please send across all workings including your code and any working files.

What we want to look at is your thought process in approaching the problem and so, please explain how you are cleaning and dissecting the data and why you are using any particular methods. All the best!
